Getting started with the glmmADMB package

Ben Bolker, Hans Skaug, Arni Magnusson, Anders Nielsen March 26, 2012

Loading required package: methods

1 Introduction/quick start

glmmADMB is a package, built on the open source AD Model Builder nonlinear fitting engine, for fitting generalized linear mixed models and extensions.

- response distributions: Poisson, binomial, negative binomial (NB1 and NB2 parameterizations), Gamma, Beta, truncated Poisson and negative binomial; Gaussian; logistic
- link functions: log, logit, probit, complementary log-log ("cloglog"), inverse, identity
- zero-inflation (models with a constant zero-inflation value only); hurdle models via truncated Poisson/NB
- single or multiple (nested or crossed) random effects
- offsets
- post-fit MCMC chain for characterizing uncertainty

As of version 0.6.5, the package has been greatly revised to allow a wider range of response and link functions and to allow models with multiple random effects. For now, the resulting package is slower than the old (single-random-effect version), but we hope to increase its speed in the future.

In order to use glmmADMB effectively you should already be reasonably familiar with generalized linear mixed models (GLMMs), which in turn requires familiarity with (i) generalized linear models (e.g. the special cases of logistic, binomial, and Poisson regression) and (ii) 'modern' mixed models (those working via maximization of the marginal likelihood rather than by manipulating sums of squares).

In order to fit a model in glmmADMB you need to:

- specify a model for the fixed effects, in the standard R (Wilkinson-Rogers) formula notation (see ?formula or Section 11.1 of the Introduction to R. Formulae can also include offsets.
- specify a model for the random effects, in the notation that is common to the nlme and lme4 packages. Random effects are specified as e|g, where e is an effect and g is a grouping factor (which must be a factor variable, or a nesting of/interaction among factor variables). For example, the formula would be 1|block for a random-intercept model or time|block for a model with random variation in slopes through time across groups specified by block. A model of nested random effects (block within site) would be 1|site/block; a model of crossed random effects (block and year) would be (1|block)+(1|year).

Random effects can be specified either in a separate random argument (as in nlme) or as part of the model formula (as in lme4).

- choose the error distribution by specifying the family (as a string: e.g. "poisson" or "binomial")
- specify a link function (as a string: e.g. "logit" or "log".
- optionally specify that zero-inflation is present zeroInflation=TRUE. In the current version, zero-inflation can only be specified as a single constant term across the entire model i.e. it cannot vary across groups or with covariates.

2 Owls data

These data, taken from [3] and ultimately from [2], quantify the number of negotiations among owlets (owl chicks) in different nests *prior* to the arrival of a provisioning parent as a function of food treatment (deprived or satiated), the sex of the parent, and arrival time. The total number of calls from the nest is recorded, along with the total brood size, which is used as an offset to allow the use of a Poisson response.

Since the same nests are measured repeatedly, the nest is used as a random effect. The model can be expressed as a zero-inflated generalized linear mixed model (ZIGLMM).

First we draw some pictures (Figures 1, 2).

Load the glmmADMB package to get access to the Owls data set; load the ggplot2 graphics package.

```
library("glmmADMB")
library("ggplot2")
```

Various small manipulations of the data set: (1) reorder nests by mean negotiations per chick, for plotting purposes; (2) add log brood size variable (for offset); (3) rename response variable.

(If you were really using this data set you should start with summary(Owls) to see what columns are there and what their characteristics are.)

Now fit some models:

The basic glmmadmb fit — a zero-inflated Poisson model.

```
fit_zipoiss <- glmmadmb(NCalls ~ (FoodTreatment +
   ArrivalTime) * SexParent + offset(log(BroodSize)) + (1 |
   Nest), data = Owls, zeroInflation = TRUE, family = "poisson")</pre>
```

```
summary(fit_zipoiss)
##
## Call:
## glmmadmb(formula = NCalls ~ (FoodTreatment + ArrivalTime) * SexParent +
```

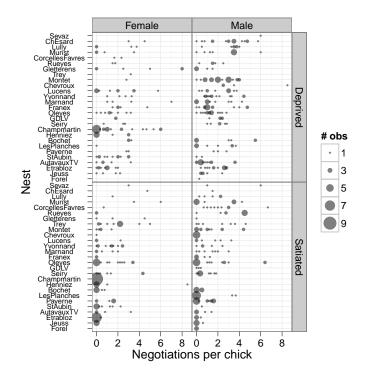

Figure 1: Basic view of owl data (arrival time not shown).

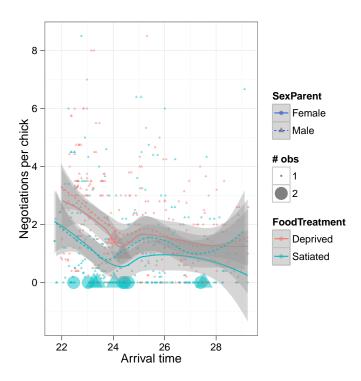

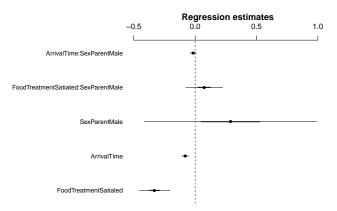

Figure 2: Basic view of owl data, #2 (nest identity not shown)

```
##
       offset(log(BroodSize)) + (1 | Nest), data = Owls, family = "poisson",
##
       zeroInflation = TRUE)
##

```

The coefplot2 package knows about glmmadmb fits:

```
library("coefplot2")
coefplot2(fit_zipoiss)
```

We can also try a standard zero-inflated negative binomial model; the default is the "NB2" parameterization (variance = $\mu(1 + \mu/k)$).

```
fit_zinbinom <- glmmadmb(NCalls ~ (FoodTreatment +
    ArrivalTime) * SexParent + offset(log(BroodSize)) + (1 |
    Nest), data = Owls, zeroInflation = TRUE, family = "nbinom")</pre>
```

Alternatively, use an "NB1" fit (variance = $\phi \mu$).

```
fit_zinbinom1 <- glmmadmb(NCalls ~ (FoodTreatment +
    ArrivalTime) * SexParent + offset(log(BroodSize)) + (1 |
    Nest), data = Owls, zeroInflation = TRUE, family = "nbinom1")</pre>
```

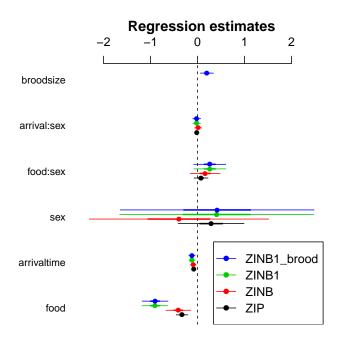

Relax the assumption that total number of calls is strictly proportional to brood size (i.e. using log(brood size) as an offset):

```
fit_zinbinom1_bs <- glmmadmb(NCalls ~ (FoodTreatment +
    ArrivalTime) * SexParent + BroodSize + (1 | Nest), data =
Owls,
    zeroInflation = TRUE, family = "nbinom1")</pre>
```

Every change we have made so far improves the fit — changing distributions improves it enormously, while changing the role of brood size makes only a modest (-1 AIC unit) difference:

```
## fit_zinbinom1 1.2 9
## fit_zinbinom 68.7 9
## fit_zipoiss 637.0 8
```

Compare the parameter estimates:

2.1 Hurdle models

In contrast to zero-inflated models, hurdle models treat zero-count and non-zero outcomes as two completely separate categories, rather than treating the zero-count outcomes as a mixture of structural and sampling zeros.

As of version 0.6.7.1, glmmADMB includes truncated Poisson and negative binomial familes and hence can fit hurdle models. The two parts of the model have to be fitted separately, however. First we fit a truncated distribution to the non-zero outcomes:

```
fit_hnbinom1 <- glmmadmb(NCalls ~ (FoodTreatment +
    ArrivalTime) * SexParent + BroodSize + (1 | Nest), data =
subset(Owls,
    NCalls > 0), family = "truncnbinom1")
```

Then we fit a model to the binary part of the data (zero vs. non-zero). In this case, I started by fitting a simple (intercept-only) model with intercept-level random effects only. This comes a bit closer to matching the previous (zero-inflation) models, which treated zero-inflation as a single constant level across the entire data set (in fact, leaving out the random effects and just using glmmADMB(nz~1,data=0wls,family="binomial"), or glm(nz~1,data=0wls,family="binomial"), would be an even closer match). I then fitted a more complex binary model — this is all a matter of judgment about how complex a model it's worth trying to fit to a given data set — but it does look as though the zero-inflation varies with arrival time and satiation.

```
Owls$nz <- as.numeric(Owls$NCalls > 0)
fit_count <- glmmadmb(nz ~ 1 + (1 | Nest), data = Owls,</pre>
    family = "binomial")
fit_ccount <- glmmadmb(nz ~ (FoodTreatment + ArrivalTime) *</pre>
    SexParent + (1 | Nest), data = Owls, family = "binomial")
AICtab(fit_count, fit_ccount)
##
              dAIC df
## fit_ccount 0.0 7
## fit_count 84.1 2
summary(fit_ccount)
##
## Call:
## glmmadmb(formula = nz ~ (FoodTreatment + ArrivalTime) * SexParent +
       (1 | Nest), data = Owls, family = "binomial")
##
##
##
## Coefficients:

2.2 Testing and inference

(Sketchy: to be expanded.)

There are many challenging statistical issues surrounding tests of terms in GLMMs. Most often people use minor variations of existing approaches (Wald tests, likelihood ratio tests, etc.), either accounting for or sweeping under the rug some of the differences that should be accounted for when moving either from linear mixed models (LMMs) or generalized linear models (GLMs) to GLMMs. See http://glmm.wikidot.com/faq, or a good book on GLMMs (!!), for a discussion of these issues.

In the meantime, keeping the limitations in mind, you can

- use AIC to select models or generated weighted predictions (see example above).
- use anova to perform a likelihood ratio test:

```
anova(fit_zipoiss, fit_zinbinom)

## Analysis of Deviance Table

## ## Model 1: NCalls ~ (FoodTreatment + ArrivalTime) * SexParent + offset(log(BroodSize))

## Model 2: NCalls ~ (FoodTreatment + ArrivalTime) * SexParent + offset(log(BroodSize))

## NoPar LogLik Df Deviance Pr(>Chi)

## 1 8 -1985

## 2 9 -1700 1 570 <2e-16 ***

## ---

## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1</pre>
```

• use Anova from the car package to generate Wald tests:

```
car::Anova(fit_zinbinom)
## Analysis of Deviance Table (Type II tests)
## Response: NCalls
##
                          Df Chisq Pr(>Chisq)

2.3.1 Convert glmmADMB parameters to lme4

this section is UNDER CONSTRUCTION

```
library("lme4") ## requires DEVELOPMENT version of lme4 ...
new_lme4 <- packageVersion("lme4") > "0.999375.42"
if (new_lme4) {
    lme4fun <- update(gm1_lme4, devFunOnly = TRUE)
    deviance(gm1_lme4)
    lme4fun(c(0, fixef(gm1_lme4))) ## variance set to zero
    v1 <- getME(gm1_lme4, "theta") ## log-Cholesky factor: equal
in this case to standard dev
    lme4fun(c(v1, fixef(gm1_lme4))) ## observed variance
(*almost* identical)
    v2 <- sqrt(gm1_glmmADMB$S[[1]])
    lme4fun(c(v2, fixef(gm1_lme4))) ## ???
}</pre>
```

```
## FIXME: figure out why this crashes knitr in
  non-interactive mode!!
## (then turn evaluation back on)
glmmadmbfun \leftarrow function(pars, minval = \exp(-9.5),
    verbose = FALSE) {
    if (pars[1] == 0) {
        warning(sprintf("variance parameter set to min val (%f)",
            minval))
        pars[1] <- minval</pre>
    }
    g0 <- glmmadmb(cbind(incidence, size - incidence) ~ period +
        (1 | herd), data = cbpp, family = "binomial", extra.args
= c("-maxfn 1 - phase 6"),
        verbose = verbose, start = list(RE_sd = log(pars[1]),
            fixed = pars[-1]))
    -logLik(g0)
}
## glmmadmbfun(c(0,fixef(gm1_lme4))) ## fails
v2B <- glmmadmbfun(c(v2, fixef(gm1_lme4)))</pre>
```

```
v1B <- glmmadmbfun(c(v1, fixef(gm1_lme4)))
all.equal(v1B, v2B, -logLik(gm1_glmmADMB))</pre>
```

2.4 MCMC fitting

AD Model Builder has the capability to run a *post hoc* Markov chain to assess variability — that is, it uses the MLE as a starting point and the estimated sampling distribution (variance-covariance matrix) of the parameters as a candidate distribution, and "jumps around" the parameter space in a consistent way (Metropolis-Hastings?) to generate a series of samples from a posterior distribution of the parameter distribution (assuming flat priors: please see the ADMB documentation, or [1], for more details).

This is very convenient, but tends to be a bit slow. In the example below, I ran a chain of 50,000 MCMC iterations — on examination, the default chain of 1000 iterations was much too short — which took about 1.04 hours on a modern (2012) desktop.

```
OwlModel_nb1_bs_mcmc <- glmmadmb(NCalls ~ (FoodTreatment +
    ArrivalTime) * SexParent + BroodSize + (1 | Nest), data =
Owls,
    zeroInflation = TRUE, family = "nbinom1", mcmc = TRUE,
    mcmc.opts = mcmcControl(mcmc = 50000))</pre>
```

Convert the MCMC chain to an mcmc object which the coda package can handle:

```
library("coda")
m <- as.mcmc(OwlModel_nb1_bs_mcmc$mcmc)</pre>
```

```
mcmc_transform <- function(m, fit) {
    if (missing(fit)) {
        fit0 <- fit
        m <- fit$mcmc
        fit <- fit0
    }
    if (!is(m, "mcmc"))
        stop("m must be an 'mcmc' object")
    if (!is(fit, "glmmadmb"))
        stop("fit must a 'glmmadmb' object")

## zero-inflation

pz <- m[, "pz", drop = FALSE]
    t_pz <- pz ## (not transformed)

## fixed effects</pre>
```

```
fixed <- m[, grep("^beta", colnames(m)), drop = FALSE]</pre>
    t_fixed <- as.mcmc(fixed %*% fit$phi)
    colnames(t_fixed) <- names(fixef(fit))</pre>
    ## variance parameters: log std dev
    theta <- m[, grep("^tmpL", colnames(m)), drop = FALSE]</pre>
    t_theta <- exp(theta)
    ## corr parameters ('offdiagonal elements of
       cholesky-factor of correlation matrix')
    corr <- m[, grep("^tmpL1", colnames(m)), drop = FALSE]</pre>
    t_corr <- corr
    ## scale/overdispersion parameter
    logalpha <- m[, grep("^log_alpha", colnames(m)), drop =</pre>
FALSE]
    t_alpha <- matrix(exp(logalpha), dimnames = list(NULL,</pre>
        "alpha"))
    ## random effects
    re \leftarrow m[, grep("^u\\.[0-9]+", colnames(m)), drop = FALSE]
    t_re <- re
    mcmc(cbind(t_pz, t_fixed, t_theta, t_corr, t_alpha, t_re),
        start = start(m), end = end(m), thin = frequency(m))
}
```

Look at the trace plots. (Something a bit odd happens at the end of the chain, so we drop the last few values ... there may be a bug in the import-handling for MCMC for very long chains ...)

```
library("scapeMCMC")
plotTrace(tm)
```

pz	(Intercept)	reatmentSa	ArrivalTime	xParentMa	BroodSize	tSatiated:S

The most frequently used diagnostic, Gelman-Rubin (gelman.diag), requires multiple chains. The full set of diagnostic functions available in coda is:

[1] autocorr.diag gelman.diag geweke.diag heidel.diag raftery.diag

effectiveSize gives the effective length of the chain for each variable, i.e. the number of samples corrected for autocorrelation:

```
range(effectiveSize(tm))
## [1] 221.5 527.9
```

HPDinterval gives the highest posterior density (credible interval):

```
detach("package:lme4") ## kluge!!
head(HPDinterval(tm))
##
                            lower
                                     upper
## pz
                          0.04298 0.14201
## (Intercept)
                          2.64801 5.94767
## FoodTreatmentSatiated -1.19929 -0.68662
## ArrivalTime
                         -0.18632 -0.06142
## SexParentMale
                         -1.71678 2.19173
## BroodSize
                          0.04601 0.32412
```

You might prefer inferences based on the quantiles instead:

```
head(t(apply(tm, 2, quantile, c(0.025, 0.975))))
##
                             2.5%
                                     97.5%
## pz
                          0.04603
                                   0.14935
## (Intercept)
                          2.57679 5.87872
## FoodTreatmentSatiated -1.19408 -0.66973
## ArrivalTime
                         -0.18398 -0.05809
## SexParentMale
                         -1.51902 2.52424
## BroodSize
                        0.05040 0.34938
```

You can also look at density plots or pairwise scatterplots ("splom" in lattice and scapeMCMC, for Scatterplot matrices), although these are not particularly useful for this large a set of parameters:

```
plotDens(tm)
plotSplom(tm, pch = ".")
```

The MCMC output in glmmADMB is currently in a very raw form — in particular, the internal names and scales of the parameters are used:

pz zero-inflation parameter (raw)

beta fixed-effect parameter estimates: **note** that these are the versions of the parameters fitted internally, using an orthogonalized version of the original design matrix, not the original coefficients. These can be converted to the original using the phi matrix as noted in the "Details" section of <code>?glmmadmb</code>

tmpL variance-covariance parameters (log-standard-deviation scale)

tmpL1 correlation/off-diagonal elements of variance-covariance matrices ("off-diagonal elements of the Cholesky factor of the correlation matrix'). (If you need to transform these to correlations, you will need to construct the relevant matrices with 1 on the diagonal and compute the cross-product, CC^T (see tcrossprod); if this makes no sense to you, contact the maintainers ...)

log_alpha log of overdispersion/scale parameter

u random effects (unscaled: these can be scaled using the estimated randomeffects standard deviations from VarCorr())

If you need to use the MCMC output and can't figure out how, please contact the maintainers and encourage them to work on them some more (!)

3 Other information

The standard set of accessors is available:

coef extract (fixed-effect) coefficients

fixef a synonym for coef, for consistency with nlme/lme4

ranef extract random effect coefficients ("BLUPs" or "conditional modes")

residuals extract (Pearson) residuals

fitted fitted values

predict predicted values (based only on fixed effects, not on random effects), possibly with standard errors (based only on uncertainty of fixed effects), possibly for new data

logLik extract log-likelihood

AIC extract AIC

summary print summary

stdEr extract standard errors of coefficients

vcov extract estimated variance-covariance matrix of coefficients

VarCorr extract variance-covariance matrices of random effects

confint extract confidence intervals of fixed-effect coefficients

In case this list is out of date, you can try methods(class="glmmadmb") to tell you what methods are currently available.

4 To do/road map

4.1 Vignette

- More examples
- Show how to specify starting values

- fix MCMC! Apply phi, std dev
- General troubleshooting (extra arguments, running outside R)
- basic intro to R2admb?
- (appendix?) document details of TPL file robustness hacks, etc.

4.2 Code

- Speed improvement by identifying special cases?
- Spatial models?
- Additional flexibility:
 - Allow model specification for zero-inflation
 - Allow model specification for shape parameter
 - More complex variance models (see AS-REML/MCMCglmm for interface/syntax ideas)
- Improve predict method: allow prediction based on REs
- simulate method
